Judging scoresheet

One sheet per team · suggested criteria, to be aligned with the panel’s rubric

criterion	what a 5 looks like (a 1 is the opposite)	score 1–5
Problem and people	A real need, named end users or stakeholders who were actually consulted; the team can say who is affected when the system is wrong.	___
Principle made concrete	The responsible-AI principle(s) claimed (fairness, transparency, privacy, safety, governance, sustainability) show up in the <i>product</i> : a design choice, a measurement, a control — not only in the slides.	___
Evidence, with its scope	Every number comes with the inputs it was measured on. “96 % accurate” says <i>on what</i> . No claim is wider than its evidence.	___
Assurance argument	At least one requirement is stated as a property over a region of inputs (“for every ... in ..., the system must ...”), with how it was — or could be — checked, and what a counterexample would look like.	___
Honesty about limits	What is out of scope, which assumptions are load-bearing, what fails first and what happens then (human oversight, monitoring, fallback).	___
Accountability	Who chooses the thresholds, who signs off, and how an affected person finds out and contests a decision.	___
Progress and craft	A visible MVP → Alpha → Beta → final trajectory; something that works end to end; feedback from mentors and users was used.	___
Communication	Clear to a non-specialist in the room; the team distinguishes what they know from what they hope.	___
total (of 40)		___

Tie-breakers. Prefer the team that (1) can name the counterexample that would change their mind, (2) shows a decision sheet or worksheet with the blanks filled in — including *out of scope*, and (3) turned a stakeholder’s objection into a change in the product.

Notes for feedback (one strength, one risk, one question to take home):
